

POOLS AND SPAS NEED TO BE PROTECTED AGAINST THEIR MAJOR POLLUTANT – PEOPLE!

Bacteria will grow in any untreated body of water. Swimmers are the primary source along with top-up water, leaves, grass, dust, etc. Animals also contribute. A large dog contributes twenty times as much as a human. Bacteria are a serious health risk and need to be killed quickly and effectively. Adding a sanitiser [usually a chlorine] to the water regularly will do just that.

The filter removes dead bacteria and the "residual sanitiser" left in the water will kill any new bacteria immediately.

Most bacteria will be killed when exposed to a "free chlorine residual" as low as one milligram per litre or one part per million (ppm).

Regularly water testing and adding the required amount of chlorine will maintain a residual level of 1.0 or 2.0 ppm easily.

TYPES OF CHLORINE

Chlorine is available in granular, liquid, or tablet form, and can be stabilised or unstabilised. A salt-water chlorinator can also generate it. Each form has its features and benefits.

Granular chlorine is convenient, easy to store and relatively cheap, but cannot be dosed automatically.

Liquid chlorine is bulky and can't be stored for long periods, but can be dosed automatically. All work effectively, so consult your pool shop for expert advice.

Safety Note: Never mix chemicals – even different types of chlorine - fire and/or explosion may result

SALT CHLORINATORS

As the name suggests, these units generate chlorine by passing the pool water through a process of electrolysis to convert sodium chloride (salt) into hypochlorous acid. They come in different sizes to suit different pools so select one that is able to produce sufficient chlorine for your needs. Even then, you may still need to add extra chlorine from time to time to maintain a satisfactory residual level.

STABILISER

Stabiliser, or isocyanuric acid is combined with chlorine, to protect it from UV rays, which drastically reduce its effectiveness. Stabiliser can also be added manually to the pool.

Check the level of stabiliser in the water periodically. Stabiliser is not consumed like other chemicals in the pool, so it can build up to levels high enough to inhibit the effectiveness of the chlorine.

CHLORINE ODOUR

A strong chlorine smell doesn't mean too much chlorine, it may mean too little.

Sanitising can produce chloramines and these produce odour, sore eyes and itchy skin. To remove them, add a boost of "superchlorination", but always consult your pool shop first.
